TITLE: New kinds of push-pull pulse-duration modulation and some problems concerning their theory

SOURCE: IVUZ, Radiotekhnika, v. 9, no. 6, 1966, 703-713

TOPIC TAGS: pulse modulation, modulation spectrum, pulse phase modulation, pulse duration modulation, pulse width modulation, pulse position modulation

ABSTRACT: New principles for selecting a continuous signal for its temporary discretization are examined, and on their basis new concepts of push-pull pulse-width modulation of the third and fourth kinds are introduced. The pulse spectra of such modulations are found. The accuracy of signal reflection in the pulse series with a push-pull pulse-width modulation of the third kind is evaluated. The merits of the new kinds of modulation and their utility in a series of systems and installations are shown. The new principles for selecting discrete-signal values can also be used effectively with other types of pulse modulation, such as single-

can be eliminated by simple measures. The authors believe that the pulsed amplifier is less reliable than the corresponding conventional amplifiers, due to its greater complexity. On the other hand, gas-filled devices can be used for this application, thereby increasing the reliability. There are 6 figures and 6 Soviet references.

TITLE: Experimental development of an audio-frequency pulsed power amplifier

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy, Radiotekhnika, 1961, Vol.4, No.2, pp.204-207

TEXT: The purpose of this brief note is to describe experiments for determining the usefulness of pulse amplification for high power audio signal amplification. The amplifier developed had a power of 1200 W and an efficiency about 50%, with quality corresponding to class-B amplifiers. Symmetrical pulse-width modulation was used, with triangular pulses, passing into pulse amplitude modulation at low levels. The output stages were triodes, operating with positive grid. At 1000 cps, the output power was 1250 W with an efficiency of 50%, while at moderate signal level the efficiency was 10%. This compares with the efficiencies of existing amplifiers of 30% at maximum signal level and 3 to 4% at medium levels. The experimental amplifier developed 4 to 5% nonlinear distortion, which the authors claim Card 1/2

rate i_2/C . Since i_2 is stabilized, the voltage across the capacitance changes linearly. In the final circuit, the voltages E_1 , E_2 and E_3 can be derived from suitable potential dividers and a diode can be introduced for clamping the potential level at the grid of the first tube. The circuit was investigated experimentally and it was found that it is satisfactory and gives good linearity. There are 2 figures and 1 Soviet reference.

negative current feedback so that this tube together with its elements R_1 and E_1 forms a current stabilizing bipole (Ref.1). The second tube and the elements R_2 and E_2 form a similar current stabilizing bipole. However, this differs from the preceding bipole in that apart from a constant voltage E_2 a variable voltage developed across the capacitance C is applied to the grid of the second tube. The influence of this voltage on the operation of this current stabilizing bipole is eliminated by applying a compensating voltage to the grid of the second tube. This voltage is equal in magnitude to the voltage across C and is opposite in phase. The compensating voltage is taken from the output of the third tube which is connected as a cathode follower. The input signal to the cathode follower is taken from the anode of the first tube, this signal being equal and opposite in phase to the voltage across the capacitance C . When a negative pulse is applied to its grid, the first tube is cut off and the current i_2 begins to flow C (as shown by the dotted line in Fig.1). Consequently, the voltage across the capacitances increases at the

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy, Radiotekhnika,
1960, No.3, pp.407-409

TEXT: The system described produces a triangular waveform in which both the rising and the falling portions are linear functions of time. A simplified circuit diagram of the device is shown in Fig.1. The generator is actuated by means of negative rectangular voltage pulses which are applied to the control grid of the first tube. In order to explain the operation of the system, the instant of the termination of the rectangular pulse is first considered. At this instant the first tube becomes conducting and its anode current is equal to the sum of currents i_1 and i_2 which are indicated in Fig.1. Current i_1 flows through the capacitance C so that the voltage across it rises linearly at a rate i_1/C (see Fig.1). In order to ensure a linear voltage rise, it is necessary to stabilize the current i_1 . This is achieved by stabilizing the anode currents of the first and the second tubes. The current of the first tube is stabilized by providing a large

with various other amplifiers. Figure 4 shows a variation of the pulse amplifier system. The authors state that several other versions may be used. Figure 5 shows a circuit diagram of a simplified practical application of a pulse amplifier for sound frequencies. It contains four "6P9" tubes and one "6N5S" tube. Measurements showed that the amplifier has an output of 2 watts at a frequency of 1 kc. The efficiency factor attains a calculated value of 84% after subtraction of all losses and it drops gradually when the signal level is reduced. At a signal level of 30% of the maximum, it was equal to 70%. The level of non-linear distortions is relatively low (between 3-6%). There are three circuit diagrams, 1 diagram and 2 graphs.

TITLE: An LF Power Amplifier with a High Efficiency Factor (Uslitel' moshchnosti NCh s vysokim KPD)

PERIODICAL: Radio, 1958, Nr 2, p 45 - 47 (USSR)

ABSTRACT: Contemporary power amplification methods of sound frequency oscillations have low energetic indexes, since their efficiency coefficients at medium transmission levels amount to only 15 - 18%. In 1951, D.V. Ageyev suggested a pulse method with a higher efficiency factor. A few years later, R. Sharbon'ye suggested another pulse amplification method. However, both methods had a number of disadvantages. The authors of this paper devised a third method which maintains the advantages of the Ageyev and Sharbon'ye methods, but does not have their disadvantages. Figure 1 shows a simplified circuit diagram which explains the essential features of pulse amplification. In case there is no signal to be amplified, all anode circuits are blocked and do not require any power from the rectifier. The energetic advantages of this amplifier are shown in Figure 3, where it is compared

MALANOV, V. V.

"A New Highly Effective Method of Power Amplification of Audio Frequency Oscillations," pp 94-98, ill, ref

Abst: The article examines a pulse method for the power amplification of audio frequency oscillations which has significantly big or energy factors than all other methods of power amplification known to this time. It is shown that with the use of this new method the tube is used only as a relay, making the energy from the source of the anode supply accessible to the load. This will make it possible to use gas-filled tubes for amplification which, with the aid of miniature ionic instruments, will provide greater power at a higher efficiency.

anode voltage. For the complete energetic characteristic of the new amplification method it is important to know what part of the power given out by the terminal amplifier corresponds to the component of the modulated frequency. For this purpose the frequency spectrum of the impulses is examined as to duration by two-cycle modulation. It was found that, in the case of a maximum signal, about 78,5% of the entire performance taken by the terminal amplifier from the source is given up in form of a sound performance as load. Consequently, the efficiency of the impulse amplifier will always be 40% higher than the degree of efficiency basing upon the ordinary method of amplification even if the energy of the highest harmonic component is not fully utilized.

Finally, the method employed for the energetic computation of the amplifier is explained. From what has been said it may be seen that the impulse method has very good characteristics, but that its application is of use only if performance is sufficiently high.

TITLE

The Impulse Method of the Efficiency Amplification of the
Oscillations of Sound Frequency.

PERIODICAL

Radiotekhnika, 11, fasc.10, 38-46 (1956)

Issued: 11 / 1956

In 1951 an impulse method for the efficiency amplification of sound frequency oscillations was suggested by D.V.AGEEV. A similar idea was expressed several years later by the Frenchman CHARBONIER. The methods of realizing this idea are, however, in both cases quite different. AGEEV'S method is demonstrated on the basis of a block scheme. The output voltage of the amplifier I, which is assumed to be sinusoidal and which is described as modulating, acts upon a two-cycle generator-modulator. 2. The latter therefore forms rectangular voltage impulses with constant frequency, the duration of which is proportional to the present value of the modulating voltage. The generator-modulator has the property of forming for one polarity of modulated voltage, a group of voltage impulses at the output of its upper shoulder which is modulated according to duration, and for the inverse polarity, it forms a group of voltage impulses at the output of the lower shoulder. These voltage impulses are conveyed to the two-cycle impulse amplifier 3 by means of an impulse output transformer. The characteristics of this method are investigated, on which occasion impulses are assumed to be strictly rectangular. The electric efficiency of the terminal amplifier is found to be equal to the coefficient of the utilization of the

TITLE: Semidirect Product of Cyclic p-Groups

PERIODICAL: Doklady Akademii nauk SSSR, 1960, Vol. 132, No. 4, pp. 762-765

TEXT: The author formulates 10 theorems without proof on the subdirect products of groups already considered in (Ref.2). Let

(2) $G_j = [\{A_1\} \dots \{A_\alpha\} \dots]$

be the decomposition of the p-group G_j into the subdirect product of cyclic subgroups with the relations

(3) $A_\alpha^{p^m} = E, A_\beta A_\alpha A_\beta^{-1} = A_\alpha^{s_{\alpha\beta}}, \alpha < \beta,$

where $s_{\alpha\beta} = N_{\alpha\beta} p^{\alpha/\beta} + 1$ ($(N_{\alpha\beta}, p) = 1$, $N_{\alpha\beta} \geq 1$ or $N_{\alpha\beta} = 0$).Theorem 3: The commutant G_j' of the p-group G_j with the decomposition (2)and the relations (3) is identical with the subgroup $\{A_1^{p^k}\}_{x\dots\dots} \times \{A_\alpha^{p^k}\}_{x\dots\dots}$

The device for automatic control of...

The automatic control device is given by the nominal power of the reactor 2000 kw. The control device itself might be used without adaptation up to 100 MW. The device enables measuring and signalising periods of the reactor up to 2,5 sec and automatic control of reactor periods up to 3,5 sec. During normal operation the working period 10/11 min including automatic self control. The Report of the Inst. Nukl. Res. USSR No. 390. The final report contains a complete documentation of the new device, i.e. e. the descriptions, figures, schemes, operation rules, and the results of device tests.

TITLE: The device for automatic control of nuclear reactor in Nez, Czechoslovakia

PERIODICAL: Jiderna Energie, no. 8, 1962, 285

TEXT: The described device controls its own ability for starting the reactor, the start of the reactor from subcritical state to the given power, power changes to given value, further the device controls whether the reactor state corresponds to the required state and also its own function. The malfunctioning system is disconnected. In the case of failure of the regulator the device automatically transfers the power or periods regulating function to another system. Corrections of control rod position are made also automatically. Three impulsion fission chamber are used as movable detectors for the whole range of reactor power changes. The minimum power regulated automatically is 10 W and this value is also the lower limit of the application of automatic regulator of positive and negative periods. The upper limit of the scope
